Caller identification revolutionized the art of avoidance. If you did not want to talk to one individual person, all of the sudden, you were able to make an intelligent decision whether or not you would like to answer the phone instead of never answering or the obvious using your answering machine to screen calls. But I don't feel like this is enough. Sometimes, I want to talk to my mother (like when she just wants to chat) sometimes I don't (like when she is going to nag me). Caller ID is not going to help this situation. This problem could be solved if cell phones were able to predict the user's mood. One instance of this could be that the cell phone would have sensors that could measure sweat, heart rate, force of button pushing (or if it is voice activated the tone of voice), etc. to predict the caller's mood and then the ringtone on the receiving end would change dependent upon the caller's mood.
