Visualization for Social Networks based on email or chat data

A tool to look at a user’s wall-to-wall data from a facebook account.

The clouds represent key words or items that propelled conversation between you and other people. Links would have their own category. For instance, you could see if a lot of conversation between you and somebody is more than just saying hi every once in a while. In every month new words would appear, so that a user could get a sense of conversation history over time. I expect that for a lot of people there will only be one or two things said over long distances of time, but it may be interesting to see if certain words appear before gaps in conversation. Mood could show up for instance. Additionally, looking at a user’s wall-to-wall posts with all of a their friends in aggregate should show how this person maintains contact with large groups of people.

Size of the clouds represents frequency.
