My visualization takes input from 2 video sources. Ideally this would accompany a webcam program. The program will display the current video state of the 2 video sources at the bottom of the visualization. As the two people talk, snapshots of the video will be taken and displayed below them in order. The rate at which these samples will be taken will depend on the audio for each of these videos. This will result in a focus on the person who is “ideally” controlling the conversation and displaying a history of the conversation.
